Problem: visualize the holes in a digital object

Why? Identify errors, measure holes

Approach:

- Visualize holes as homology cyles ( $\sim$ discrete manifolds)

■ Short cycles are better (tight, well located)

Computing a minimal homology basis

- size of cycle: number of cells
- $q=1: \mathcal{O}\left(n^{\omega}+n^{2} \cdot \beta_{1}\right)^{1}$

■ $q>1$ : NP-hard ${ }^{2}$

${ }^{1}$ Dey et al: Efficient algorithms for computing a minimal homology basis (2018)
${ }^{2}$ Chen and Friedman: Hardness results for homology localization (2011)

Computing a minimal radius homology basis
■ size of cycle: radius of smallest geodesic ball containing it

- $q \geq 1: \mathcal{O}\left(\beta_{q} \cdot n^{4}\right)^{3}$, then $\mathcal{O}\left(n^{\omega+1}\right)^{4}$
- Theoretical algorithm, not implemented

${ }^{3}$ Chen and Friedman: Measuring and computing natural generators for homology groups (2011)
${ }^{4}$ Dey et al: Efficient algorithms for computing a minimal homology basis (2018)

Goal: we want an algorithm that
1 can be implemented in practice
2 is faster (even if it is worse)

Sketch of persistent homology computation:

- Sort cells according to the filtration
- For each cell, associate it with one of the previous ones
- Each of these pairs makes a persistence pair

## Persistence pairs

$P D(F)=\left\{(i, j)\right.$ with multiplicity $\left.\mu_{i, j}\right\}$
We also obtain:

- A partial matching of cells
- A cycle associated to each pair ( $\simeq$ hole)

4 Conclusion

## Homological Discrete Vector Field

Let $K$ be a cubical complex and $P, S \subset K, P \cap S=\emptyset$. $(P, S)$ is a HDVF if $j_{P} \circ \partial \circ i_{S}$ is an isomorphism.
where

- is : $S \rightarrow K$ inclusion
- $j_{P}: K \rightarrow P$ projection
( $j_{P} \circ \partial \circ$ is) is an invertible submatrix of the boundary matrix

$$
\partial_{1}=\left[\begin{array}{llll}
1 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 1
\end{array}\right] \quad \partial_{2}=\left[\begin{array}{l}
1 \\
1 \\
1 \\
1
\end{array}\right]
$$

$$
\partial_{1}=\left[\begin{array}{llll}
1 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 1
\end{array}\right] \quad \partial_{2}=\left[\begin{array}{l}
1 \\
1 \\
1 \\
1
\end{array}\right]
$$

$P=\{1,2,3,4\}, S=\{a, b, c, d\}$ is not a HDVF (not invertible)

$$
\partial_{1}=\left[\begin{array}{llll}
1 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 1
\end{array}\right] \quad \partial_{2}=\left[\begin{array}{l}
1 \\
1 \\
1 \\
1
\end{array}\right]
$$

$P=\{1,2,3,4\}, S=\{a, b, c, d\}$ is not a $\operatorname{HDVF}$ (not invertible)
$P=\{1,2,3, a\}, S=\{a, b, c, A\}$ is not a $\operatorname{HDVF}(P \cap S \neq \emptyset)$

$$
\partial_{1}=\left[\begin{array}{llll}
1 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 1
\end{array}\right] \quad \partial_{2}=\left[\begin{array}{l}
1 \\
1 \\
1 \\
1
\end{array}\right]
$$

$P=\{1,2,3,4\}, S=\{a, b, c, d\}$ is not a HDVF (not invertible)
$P=\{1,2,3, a\}, S=\{a, b, c, A\}$ is not a $\operatorname{HDVF}(P \cap S \neq \emptyset)$
$P=\{1,2,3, d\}, S=\{a, b, c, A\}$ is a HDVF

A maximal HDVF provides:

- A homology basis
- A cohomology basis
- Check if a cycle is trivial

■ Check if two cycles are homologous

2 Keep the shortest cycles that make a homology basis

General case: more than one hole
1 Get some candidate (non trivial) cycles
2 Keep the shortest cycles that make a homology basis

## Pitfalls:

1 How to find good candidate cycles?
2 A cycle is trivial or not?
3 A set of cycles is a homology basis?

Description

## Outline

## 1 Introduction

## 2 Background

3 Algorithm

- Description
- Comparison
- Results

4 Conclusion

Our algorithm has 4 steps
1 Breadth balls (good starting points)
2 Compute filtrations (candidate cycles)
3 Sort and annotate (cycles to classes)
4 Earliest basis (shortest homology basis)

Notation:

- $K$ is the cubical complex of a digital object $O$
- We fix $q \geq 1$ and we look for a short homology basis for $H_{q}(K)$
- $g:=\operatorname{dim}\left(H_{q}(K)\right)$

## Step 1 - Breadth balls

- Full ${ }^{6}$ cubical complex + signed distance function $f_{s d t}=$ filtration

■ Compute partial matching $M=\left\{\left(\sigma_{1}, \tau_{1}\right) \ldots\right\}$

- Get $\mathcal{B}=$ cells $\tau$ such that

1 $(\sigma, \tau) \in M$
$2 f_{\text {sdt }}(\sigma)<0<f_{\text {sdt }}(\tau)$
$3 \operatorname{dim}(\sigma)=q$
These are the centers of the breadth balls of the digital object $O$
${ }^{6}$ Other approaches: convex hull, homotopical closing

L Algorithm

- Description

Step 1 - Breadth balls

## Step 2 - Compute filtrations

For each $\tau \in \mathcal{B}(\tau \notin K)$, we compute a discrete geodesic transform:

## Discrete geodesic transform

Let $K$ be a cubical complex, $\tau_{0} \in K$ a 0 -cube,

$$
f_{K, \tau_{0}}(\sigma)= \begin{cases}\text { size of shortest path to } \tau_{0} & \text { if } \operatorname{dim}(\sigma)=0 \\ \max \left\{f_{K, \tau_{0}}\left(\sigma^{\prime}\right): \sigma^{\prime} \subset \sigma, \operatorname{dim}\left(\sigma^{\prime}\right)=0\right\} & \text { if } \operatorname{dim}(\sigma)>0\end{cases}
$$

## Step 2 - Compute filtrations

Then, for each $\tau \in \mathcal{B}$

- Let $\tau_{0} \in K$ be a closest 0 -cube to $\tau$
- $f_{K, \tau_{0}}$ is a filtration over $K$

■ Persistent homology computation $\rightarrow\left\{x_{1} \ldots x_{g}\right\}$ a homology basis for $K$

- $|\mathcal{B}|=g \Rightarrow$ we compute $g$ homology bases $=g^{2}$ cycles

## Step 3 - Sort and annotate

We sort the $g^{2}$ cycles by size: $\left\{x_{1} \ldots x_{g^{2}}\right\}$

To find a basis, we need to write these cycles in a homology basis: an annotation

## Annotation

Homomorphism a: $K_{q} \rightarrow H_{q}(C)$ such that for any two q-cycles $x, y, a(x)=a(y)$ iff $[x]=[y]$.

This is simply a linear map that projects each cycle onto the homology group, a $g \times\left|K_{q}\right|$ matrix.

## Step 3 - Sort and annotate

$$
H_{1}(K)=\left\langle e_{1}, e_{2}\right\rangle
$$

## Step 3 - Sort and annotate

L Algorithm
$L_{\text {Description }}$

## Step 3 - Sort and annotate

L Algorithm
L Description

## Step 3 - Sort and annotate

$$
\begin{aligned}
& H_{1}(K)=\left\langle e_{1}, e_{2}\right\rangle \\
& a(x)=e_{1}+e_{2}
\end{aligned}
$$

## Step 3 - Sort and annotate

We compute an annotation with a HDVF:
1 Let $M=\bigcup_{i \in I}\left\{\left(\sigma_{i}, \tau_{i}\right)\right\}$ be the partial matching of cells computed by any of the filtrations in Step 2
2 Define $P:=\{\sigma:(\sigma, \tau) \in M, \operatorname{dim}(\sigma)=q\}$ and $S:=\{\tau:(\sigma, \tau) \in M, \operatorname{dim}(\tau)=q+1\}$
$3(P, S)$ is a HDVF and the linear map (matrix)

$$
a=\left(j_{C} \circ \partial_{q+1} \circ i_{S}\right) \circ\left(j_{P} \circ \partial_{q+1} \circ i_{S}\right)^{-1} \circ j_{P}+j_{C}
$$

is an annotation
4 Computation: get $A=\left(j c \circ \partial_{q+1} \circ i_{S}\right), B=\left(j p \circ \partial_{q+1} \circ i_{S}\right)$, and compute $A \cdot B^{-1}$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 \\
1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0
\end{array}\right]
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 \\
1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0
\end{array}\right] \quad \text { col: } 1
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0
\end{array}\right] \quad \text { col: } 1
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0
\end{array}\right] \quad \text { col: } 2
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1
\end{array}\right] \quad \text { col: } 2
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1
\end{array}\right] \quad \text { col: } 6
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles

$$
\left[\begin{array}{lllllllll}
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0
\end{array}\right] \quad \text { col: } 6
$$

## Step 4 - Earliest basis

- Let $Y$ be the $g \times g^{2}$ matrix with columns $a\left(x_{1}\right) \ldots a\left(x_{g^{2}}\right)$

■ Get the first columns to make a basis with gaussian elimination

- Return the corresponding cycles
$\left[\begin{array}{lllllllll}0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0\end{array}\right] \quad$ col: 6

4 Conclusion

Focus on the algorithm by Dey et al (2018):
1 Compute one filtration per 0-cube (fast matrix multiplication)
2 Sort all $\left|K_{0}\right| \cdot g$ cycles
3 Compute annotation (LSP-decomposition, fast matrix multiplication)
4 Earliest basis using (LSP-decomposition)
This is a theoretical algorithm using fast matrix multiplication

We simplify it to compare it with ours:
1 Compute $g$ filtrations from random 0-cubes
2 Sort all $g \cdot g$ cycles
3 Compute annotation (with a HDVF)
4 Earliest basis (with gaussian elimination)
This adaptation can be computed and has a similar time complexity

Table: Average sizes of the homology bases produced by both algorithms

Conclusion:
■ Heuristic for short homology generators

- Dey et al* is not that bad
- $\mathcal{O}\left(m^{3}+g \cdot n^{3}\right)$ time complexity

■ Easy to implement, check our code

Perspectives:

- Two step algorithm: initial solution + optimization
- Improve length (area, volume...) estimation
- Faster algorithm for the annotation
